Validation and AI use - working record

AI-assisted educational coursework; not investment advice.

The assistant researched public filings, transcribed inputs, proposed forecast assumptions, wrote Python/HTML, drafted documents and wrote automated tests. These activities must be disclosed. No independent human testing, partner cold run, instructor access, video recording or final submission is claimed.

Automated tests include an independently calculable perpetuity identity, source-total arithmetic, causal scenario ordering, predicted directional changes, nonfinite/out-of-range rejection, intentional cash-error refusal/recovery, and all 512 corners of the nine bounded controls. The source arithmetic checks transcribed totals; it is not an independent re-reading of the filing. The perpetuity is a synthetic fixture, not the required course training case. See outputs/test-results.txt for the actual test run.

The highest-risk model component cannot be established merely by accounting identities: large investment, uncalibrated segment margins and terminal reinvestment dominate economic interpretation. The student's required AI-off highest-risk claim and three failures remain unwritten. The sensitivity and reverse-DCF outputs are available for later student interpretation, without substituting for that exercise.

Human validation fields to complete: locked file/commit; timestamp before prediction; predicted direction and explanation; input changed; run timestamp; observed outcome; mismatch and resolution; independent source comparison; course training-case reconciliation; partner cold run and recovery; evidence that a consequential AI-generated assertion was accepted, corrected or rejected after independent testing.

The official course audit only checks mechanical completeness of nonempty fields. Missing access evidence remains blank. A passing finance model test does not validate access, provenance, economic assumptions or compliance with the rubric.
